

SQM Darkness Values (mags)

Understanding the effects of urbanization and artificial light at night on the wildlife activity in Fort Collins, Colorado

Reservoir Ridge
Darkest Value: 21.3
Number of Photos: 53
Species Seen: 6

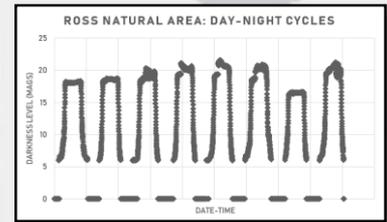

Field Methods

Two parallel transects of 31 trail cameras was in place from a Urban Wildlife Information Network project; new measurements were taken between 3/29/18 - 5/16/18.

16 of these sites were chosen to add sky quality meters (SQMs) to measure darkness levels. Four SQMs were distributed across the city to measure zenith darkness values.

Mean darkness readings at each site were compared to species information from camera traps.

Example of raw data from SQM units - shows the cycles of darkness and brightness over 8 days of the field season.

Predictions

- Sites towards the center of the city will be the brightest, while those further out will be darkest
- Species richness will be highest at the darkest sites
- Of the larger carnivores:
 - Coyotes and bobcats will be seen only in rural, dark sites
 - Red fox will be seen in natural areas within the city
- Artificial light at night may affect normal activity patterns of wildlife

Ross Natural Area
Darkest Value: 19.9
Number of Photos: 46
Species Seen: 4

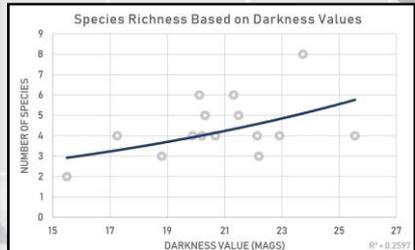

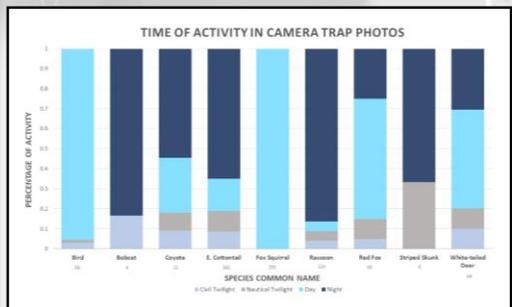

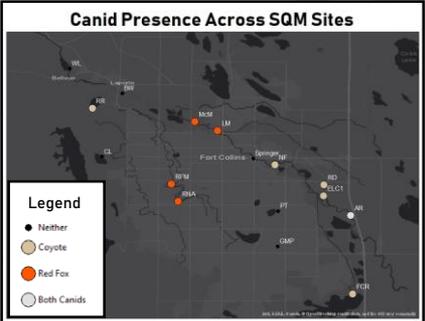

Power Trail
Darkest Value: 17.2
Number of Photos: 58
Species Seen: 4

Fossil Creek Reservoir
Darkest Value: 20.7
Number of Photos: 42
Species Seen: 4

Results

Conclusions

- SQMs measured ground illuminance, so the brightness gradient predicted across the city was not seen.
- Large carnivores (bobcats and coyotes) were isolated to sites on the outskirts of the city. Red fox were seen in bright sites within the city's natural areas. Red fox and coyote presence rarely overlapped.
- There was a slight positive correlation between species richness and the darkness of the site.
- More research is necessary to understand the impact of light on activity patterns in wildlife.
